## Solution to Sheet 5.

## Problem 1

We have basically solved this already on sheet 3. Note that as  $d_1 \mid q_1$  and  $d_2 \mid q_2$ , we have  $(d_1, d_2) = 1$ , so (by sheet 3) there are primitive characters  $\psi_i \mod d_i$  with  $\chi_i = \psi_i \chi_{0,q_i}$  (here again  $\chi_{0,q_i}$  is the principal character mod  $q_i$ ) whose product  $\psi = \psi_1 \psi_2$  is a primitive character mod  $d_1 d_2$ . Modulo q, this reveals

$$\chi_1 \chi_2 = (\chi_{0,q_1} \psi_1)(\chi_{0,q_2} \psi_2) = \chi_{0,q_1 q_2} \psi,$$

hence  $\psi$  is induced by a primitive character mod  $d_1d_2$ .

It is easily seen that the coprimality condition is necessary. Take any real character  $\chi \mod q$  for example, then  $\chi^2 = 1$  and has conducter  $1 \neq q$ .

## Problem 2

We have to show the bound

$$\int_{(-A+\frac{1}{2})} \Gamma(s) x^s \, \mathrm{d}s \ll \frac{x^{-A+1/2}}{(A-1)!}.$$

Note that the integral exists by the rapid decay of  $\Gamma$  along vertical lines. However, we cannot apply Stirling's formula to bound the integral directly as Stirling a priori only gives uniform bounds in regions of the form  $|\arg(s) - \pi| \ge \delta > 0$ . We can however apply stirlings formula if we apply the recurrence  $s\Gamma(s) = \Gamma(s+1)$  repeatedly:

$$\int_{(-A+1/2)} \Gamma(s) x^{s} \, ds \ll \int_{(-A+1/2)} |\Gamma(s) x^{s}| \, ds \ll x^{-A+1/2} \int_{(1/2)} |\Gamma(s-A)| \, ds$$

$$= x^{-A+1/2} \int_{(1/2)} \left| \frac{\Gamma(s)}{(s-A+1)\cdots(s-1)} \right| \, ds \leq \frac{x^{-A+1/2}}{(A-1)!} \int_{(1/2)} |\Gamma(s)| \, ds.$$

**Notes.** Once we know this inequality, we actually can do better: Remember that  $\Gamma$  has poles at the negative integers, the residue at -n is given by  $\frac{(-1)^n}{n!}$ . Hence for (large) T > 0, we have that

$$\int_{1/2-A-\mathrm{i}T}^{1/2-A+\mathrm{i}T} \Gamma(s) x^s \, \mathrm{d}s = 2\pi \mathrm{i} \frac{(-x)^{-A}}{A!} + \int_{1/2-A-\mathrm{i}T}^{-1/2-A+\mathrm{i}T} \Gamma(s) x^s \, \mathrm{d}s + O\left(\int_{1/2-A-\mathrm{i}T}^{-1/2-A-\mathrm{i}T} \Gamma(s) x^s \, \mathrm{d}s\right).$$

By the rapid decay of  $\Gamma$ , the horizontal integral vanishes as  $T \to \infty$ , and we can bound the vertical integral using what we showed before, applied to A + 1. This yields

$$\int_{(-A+1/2)} \Gamma(s) x^s \, ds = 2\pi i \frac{(-x)^{-A}}{A!} + O\left(\frac{x^{-A-1/2}}{A!}\right).$$

In fact, as for every x > 0 the fraction  $x^A/A!$  tends to zero as  $A \to \infty$ , we may repeat this as often as we want, obtaining

$$\frac{1}{2\pi i} \int_{(-A+1/2)} \Gamma(s) x^s \, ds = \sum_{k=A}^{\infty} \frac{(-x)^{-k}}{k!} = e^{-\frac{1}{x}} - \sum_{k=0}^{A-1} \frac{(-x)^{-k}}{k!}.$$

The equation for A = 0 is nothing new! As  $\Gamma(s)$  is holomorphic for  $\Re s > 0$  we already know that  $\mathcal{M}(e^{-x})(s) = \Gamma(s)$ , so

$$e^{-x} = \frac{1}{2\pi i} \int_{(1/2)} \mathcal{M}(e^{-x})(s) x^{-s} ds = \frac{1}{2\pi i} \int_{(1/2)} \Gamma(s) x^{-s} ds.$$

Now replace x by  $x^{-1}$ .

## Problem 3

We substitute  $p^{-s} = x$  to find the equivalent

$$\sum_{k=0}^{\infty} \beta(k) x^k = \frac{1}{P(x)}.$$

Where  $P(x) = \prod_{j=1}^{d} (1 - \alpha_j x) = \sum_{i=0}^{d} a_i x^i$  (in particular,  $a_0 = 1$ ). Multiply both sides with P, revealing

$$\sum_{d=0}^{\infty} x^d \sum_{k=0}^{d} \beta(d-k)a_k = 1.$$

Equating coefficients gives that for k > 0,

$$\sum_{k=0}^{d} a_k \beta(d-k) = 0,$$

which, after subtracting  $\beta(d)$  on both sides and setting  $c_i = -a_{i+1}$ , gives the desired recurrence.
